Diagnostic Imaging Pathways - Suspected Blunt Cerebrovascular Injury

Population Covered By The Guidance

This pathway provides guidance on the imaging of blunt trauma patients who are at increased risk of cerebrovascular injury.

Date reviewed: August 2018

Date of next review: August 2021

Pathway Diagram
New Denver Screening Criteria

Signs/symptoms of BCVI:
- Potential arterial haemorrhage from neck/nose/mouth
- Cervical bruit in a patient <50yrs
- Expanding cervical haematoma
- Focal neurologic deficit
- Neurologic examination incongruous with head CT scan findings
- Stroke on secondary CT scan

Risk Factors for BCVI; **High-energy transfer mechanism with:**
- C-spine fractures, subluxation or ligamentous injury
- Basilar skull fracture with carotid canal involvement
- Diffuse axonal injury with GCS score ≤8
- Lefort II or III fracture
- Mandible fracture *associated with high-energy transfer mechanism*
- Occipital condyle fracture *associated with high-energy transfer mechanism*
- Petrous bone fracture *associated with high-energy transfer mechanism*
- Near hanging with anoxic brain injury
- Clothesline type injury or seat belt abrasion with significant swelling, pain, or altered mental state
- Scalp degloving *associated with high-energy transfer mechanism*
- Major thoracic injuries, including vascular injuries and blunt cardiac rupture, *associated with high-energy transfer mechanism*

CT angiogram if any criterion present

- No vascular injury
  - Stop
  - No vascular injury
- New/persistent neurological deficit
- Carotid or vertebral artery injury
  - Manage appropriately
  - MRI/MRA
Blunt Cerebrovascular Injury

Image 1a (Angiogram): A carotid angiogram in a 33 year old male involved in a motor bicycle accident reveals complete occlusion of the right internal carotid artery in its supraclinoid portion (arrow).

Image 1b (Computed Tomography): Large right middle cerebral artery territory infarct with mass effect (arrow).

Teaching Points

- Blunt cerebrovascular injury (BCVI) is a rare but serious sequela of trauma that occurs in approximately 1% of all blunt trauma victims.
- Morbidity and mortality is due to stroke which occurs in 10-21% of cases. Although some cases present with stroke, a number cases are initially asymptomatic and may have a delayed neurological event 10-72 hours after trauma.
- Symptoms relate to the vascular territories of the carotid and vertebral arteries. Vertebral artery injuries can result in posterior circulation strokes which may present as motor or sensory deficits, vertigo, ataxia, visual field deficits, dysarthria, dysphagia or loss of consciousness.
- There is evidence that anticoagulation or use of antiplatelet agents reduce the rate of stroke in BCVI, so there may be benefit from screening asymptomatic patients who are at increased risk.
- The exact optimal medical treatment regimen is yet to be determined.
- Clinical screening criteria with a sensitivity approaching 100% are yet to be defined. The most commonly used modified Denver screening criteria may miss 20-37% of BCVI. The New Denver Criteria are broader and identify more BCVIs, however the trade-off is that more patients will have unnecessary investigations. 5% of BCVIs may not fit into the listed New Denver Criteria.
- The New Denver Criteria identify injuries that are associated with BCVI if they are associated with a high energy mechanism.
- CT angiogram is the non-invasive screening tool of choice for BCVI in selected patients.
- MRI/MRA may be indicated as a second-line investigation for patients with new or persistent neurological signs concerning for BCVI, but a normal CTA.
- Invasive angiography (or digital subtraction angiography, DSA) is generally only indicated for therapeutic intervention. It is considered the gold standard diagnostic test for BCVI, but it has a number of disadvantages including cost, availability, and 1% risk of adverse events including stroke.
Blunt Cerebrovascular Injury (BCVI) Screening

- BCVI is an injury to the carotid and vertebral arteries, often secondary to direct trauma.
- Incidence ranges between 0.18% - 1.63% of blunt trauma admissions, and is reportedly as high as 2.7% in patients with an Injury Severity Score (ISS) of ≥16.
- Stroke occurs in 10-21% of cases. Although some cases present with stroke, a number of cases are initially asymptomatic, and may have a delayed neurological event 10-72 hours after trauma. This presents an opportunity for early identification and avoidance of potentially significant morbidity and mortality within this typically young cohort.
- Introducing screening criteria has led to increased detection of BCVI and is associated with a reduction in mortality and delayed stroke rate following the use of antiplatelet agents or anticoagulants.
- A meta-analysis found cervical spine injury and thoracic injury were associated with a significantly increased chance of BCVI. Mandibular fractures, when associated with a high-energy transfer mechanism, were also linked to an increased risk of BCVI.
- Unfortunately no validated diagnostic criteria to select patients in which to screen for BCVI exists that approaches 100% sensitivity.
- More liberal screening criteria may be indicated to enhance detection rates. The modified Denver screening criteria have been developed to select patients who should undergo screening for BCVI however, these may miss 20-37% of BCVI.
- The New Denver Criteria are broader and identify more BCVIs, however the trade-off is that more patients will have unnecessary investigations. 5% of BCVIs may not fit into the listed New Denver Criteria.
- Non-fatal strangulation is an uncommon injury that may be missed on history taking, especially when the injury is part of domestic violence or sexual assault. There have been cases of stroke presenting up to six months after the initial injury due to carotid dissection.
- Case series suggest that if there is a history of strangulation, CTA should be considered if there is: loss of consciousness, visual changes, facial, intra-oral or conjunctival petechial haemorrhage, incontinence, dysphonia/aphonia, dyspnoea, subcutaneous emphysema or neurological signs or symptoms, even if the presentation is delayed.

Computed Tomography Angiogram (CTA)

- CT Angiography (CTA) is the recommended screening test for BCVI. It also enables the visualisation of the vertebral column and spinal canal, the aerodigestive tract and associated soft tissues of the neck.
- Metanlyses of reported trials (conducted on machines ranging from older single slice helical CT scanners to 64 slice MDCTs) report a pooled 66% sensitivity and 97% specificity compared to digital subtraction angiography (DSA). Pooled sensitivity remained ≥80% among studies using ≥16 slice scanners.
- Sensitivities and specificities of recent prospective studies using ≥16 slice CTAs compared to DSA as the gold standard range from 41-97.7% and 86-100% respectively.
- There is a false positive rate associated with CTA which precludes its replacement of DSA as the diagnostic gold standard in BCVI at present, but its non-invasiveness, rapidity and availability make CTA a popular screening modality in the trauma setting.
- Screening high-risk populations for blunt cerebrovascular injuries appears cost-effective.
- Invasive angiography (or digital subtraction angiography, DSA) is generally only indicated for...
therapeutic intervention. It is considered the gold standard diagnostic test for BCVI, but it has a number of disadvantages including cost, availability, and 1% risk of adverse events including stroke so it is not recommended for screening.

**Magnetic Resonance Imaging/Angiography (MRI/MRA)**

- Magnetic Resonance Angiography may be used as a second-line investigation for BCVI in patients with a normal CTA but ongoing or new neurological signs that are concerning for BCVI.
- Sensitivity of 47-75% has been reported. However, in many cases ventilatory and monitoring equipment are often incompatible with MRI machines. Likewise the time required to perform the scan, and inability to gain access to an acutely unwell patient, preclude the widespread use of this technique for initial screening.
